# WHY MOSAIC?

## Spatial sampling

- ▶ High spatial resolution surveys require many pixels on sky.
- ▶ At the frame rates lucky imaging requires, it becomes difficult to run a 1Kx1K CCD without getting swamped by readout noise.
- ▶ Unfortunately, current generation of EMCCDs cannot be abutted (though this is changing).

# WHY MOSAIC?

## Dynamic range

- ▶ Independent gain control is a bonus.
- ▶ Dynamic range on a single EMCCD is limited to about 10 magnitudes by electron well depth in multiplication register.  
*(Disclaimer: back of envelope calculation.)*
- ▶ Can't guide well on a saturated star.
- ▶ Ok if GS is  $Mag \approx 16$ . Potentially problematic if GS is  $Mag \approx 10$ .

# WHY MOSAIC?

## But...

- ▶ Significant hardware challenge – alignment, synchronisation, multiple control systems...
- ▶ High data rates.
- ▶ More calibration.

(See below...)

# A HARDWARE IMPLEMENTATION

# A HARDWARE IMPLEMENTATION

# FIELD TEST

# FIELD TEST

## Visitor Instrument @ 2.5m Nordic Optical Telescope

- ▶ Awarded 8 nights on sky, + technical time for setup and take-down.
- ▶ Off we went to La Palma.

# FIELD TEST

# FIELD TEST

# RESULTS?

- ▶ Minor software glitches slowed progress for first couple of days.
- ▶ Overall, system performed very well.
- ▶ Some good weather.
- ▶ Now, we had lots of data to reduce ( $\sim 8\text{TB}$ ).

# PHOTOMETRIC CALIBRATION

Specific to EMCCDs:

- ▶ Accurate on-sky gain calibration via pixel histograms is desirable (CCDs independently adjustable).
- ▶ Histogram based bias map estimation is the most robust way to separate bias pedestal and internally generated signal (i.e. dark current + clock induced charge).

# PHOTOMETRIC CALIBRATION

# PIPELINE OVERVIEW

- ▶ Custom pipeline written in C++.
- ▶ A 2 stage process, comprising **evaluation** and **reduction**. Almost always I/O limited ( $\sim 60\text{--}80\text{MB/sec}$ ).
- ▶ Make use of thread-friendly STL based containers and Intel Thread Building Blocks library to implement a 'pipeline of filters' pattern.

# PIPELINE OVERVIEW

## First, frame evaluation:

- ▶ Load frame, debias, gain normalize, subtract internally generated signal (DC + CIC).
- ▶ Interpolate GS region, cross-correlate with Airy core to estimate tip-tilt and (relative) Strehl.
- ▶ Save position and quality estimates to file.

# PIPELINE OVERVIEW

## Second, **selection and recombination**:

- ▶ Sort frames by estimated quality, selecting according to user-criteria.
- ▶ Load and calibrate, optionally applying thresholding to a copy.
- ▶ Drizzle to create final image, writing to file whenever a user-selection criteria is met.

# PIPELINE OVERVIEW

# ASTROMETRIC CALIBRATION

How do you calibrate a high-resolution mosaic detector?

# ASTROMETRIC CALIBRATION

How do you calibrate a high-resolution mosaic detector?

- ▶ Using standard binaries would take at least  $(2n-1)$  pointings per focal lens.
- ▶ So we observe a crowded field.

# ASTROMETRIC CALIBRATION

How do you calibrate a high-resolution mosaic detector?

- ▶ Using standard binaries would take at least  $(2n-1)$  pointings per focal lens.
- ▶ So we observe a crowded field.
- ▶ But: standard catalogues (2MASS, USNO) do not have the resolution (2MASS pixels are 2 arcseconds width).

# ASTROMETRIC CALIBRATION

How do you calibrate a high-resolution mosaic detector?

- ▶ Using standard binaries would take at least  $(2n-1)$  pointings per focal lens.
- ▶ So we observe a crowded field.
- ▶ But: standard catalogues (2MASS, USNO) do not have the resolution (2MASS pixels are 2 arcseconds width).
- ▶ Solution: Create own catalogues from HST/WFPC fields, cross match using custom code.

REDUCTION

PERFORMANCE

TRADEOFFS, RECOMMENDATIONS

- What resolution improvement do we obtain?

# PSF PROFILES

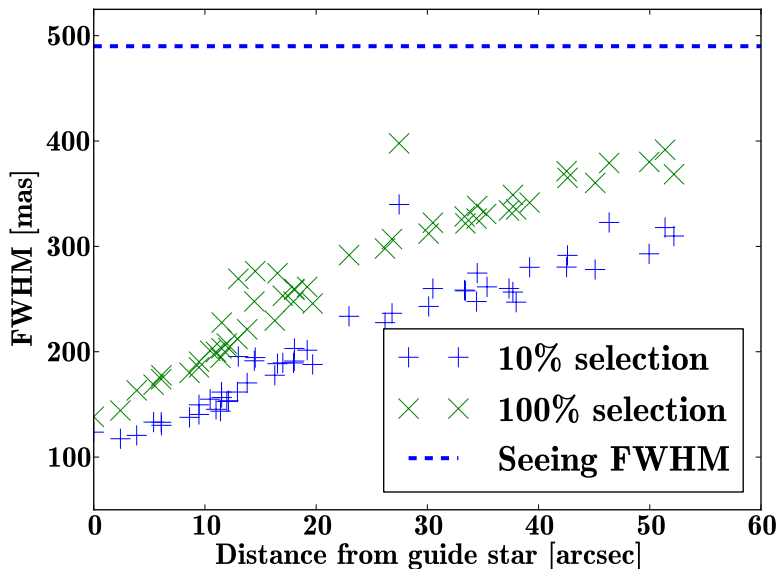

How does this vary as we move away from GS?

# FWHM ACROSS THE FIELD

# FWHM ACROSS THE FIELD

- ▶ How faint can we go?

# FAINT LIMITS: GUIDE STARS

(Simulated)

# FAINT LIMITS: GUIDE STARS

A real world example: the Einstein Cross.

(Left: HST. Right: LI. GS  $M_i \approx 17$ )

# FAINT LIMITS: SCIENCE TARGETS

## 3C 405 (Cygnus-A)

Left: HST. Right: LI.

# FAINT LIMITS: SCIENCE TARGETS

## 3C 405 (Cygnus-A)

Left: HST. Right: LI.

- ▶ One hour observation, 50% selection,  $\sim 0.5''$  seeing.
- ▶ Galaxy approx  $30''$  from guide star.
- ▶ Weakly detect stars of estimated  $M_i \geq 23$ .
- ▶ Can do better with latest hardware.

# OUTLINE

WHY MOSAIC?

LUCKYCAM 2009 & THE NOT

REDUCTION

PERFORMANCE

TRADEOFFS, RECOMMENDATIONS

# OPTIMAL PIXEL SIZE AND FRAMERATE TRADE-OFFS

- ▶ Spatial sampling vs detector noise.  
(Old issue with a new twist: Drizzle many frames with subpixel offsets.)
- ▶ Longer exposures for faint targets vs atmospheric blurring above coherence time.
- ▶ Data rates.

# OBSERVATION PLANNING

- ▶ Will there be a close / bright enough guide star?
- ▶ Will de-saturating my guide star ruin my faint limit? (Can I position the mosaic to avoid this?)
- ▶ What resolution / magnitude depth do I need to achieve, and what weather conditions / selection criteria does this require?
- ▶ (For very bright sources:) Would I be better off turning off the EM amplifier altogether?

# ASTROMETRIC CALIBRATION

- ▶ This is non-trivial!
- ▶ Worth investigating:  
`http://www.astromatic.net/  
software/scamp`  
(Cannot read custom catalogues when I last checked, but this is probably an easy feature to add.)

# OPEN QUESTIONS / RESEARCH PROBLEMS

- ▶ Use of multiple guide stars.
- ▶ Crowded field photometry with a slowly varying PSF.
